i wanna do EDA work on some defi protocol, i wanna use some tools, so i will ask how to use them in python and how to represent it graphically like using maplotlib etc, so i will ask a ceratin question and i need from you the logic behind the metric and tool, i wanna do EDA for dex aggregator protocol 1inch and compare it to cowswap paraswap etc

Thought for 3 seconds

> The user wants to perform EDA on DeFi protocols like 1inch, CowSwap, ParaSwap, and others. They want to learn how to use tools in Python and how to visualize the results. I need to provide a detailed response covering data sources, metrics, logic, Python tools, and visualization techniques. I'll follow the search plan outlined in the hints.

Found 76 web pages

> Now I need to process these search results. I have information about various APIs, SDKs, metrics, and comparisons. I'll need to synthesize this into a comprehensive guide for the user. I'll structure the response by covering key metrics, data sources, Python tools, and visualization techniques. I'll also include code examples and explanations of the logic behind the metrics.

It's a great project—comparing DEX aggregators is a fantastic way to dive deep into the core metrics that define the DeFi space. This guide will walk you through the key metrics, how to source the data using Python, and how to visualize your findings with `matplotlib` and `seaborn`.

📝 EDA Metrics & Key Concepts for DEX Aggregators

Here are the critical areas to focus on for your EDA, complete with the logic behind each and its practical significance.

Area	Concept	Logic Behind It	Si
Volume	**Total Trade Volume** (USD)	Count of total dollar value swapped within a period.	**M** sh ac
Market Share	% of total DEX agg volume	Your volume / Total market volume, as seen in reports.	**C** Tr

			ar
User Activity	**Active Traders, # of Trades** & Avg. Trade Size	Analyze user behavior patterns.	**Er** cc re in
Fees & Costs	**Direct Swap Fee** vs. **Total Transaction Cost (incl.** `gas` **)**	Total user cost is `gas` + protocol fee.	**Us** ar hi
Slippage & Execution	**Slippage** (Expected vs. Actual), Failure Rate (Reverts)	Difference in price at which a swap is executed vs. when it was quoted.	**Ex** sli us
Liquidity	**# Unique Liquidity Sources** (DEX Pools)	More integrated DEXs means better prices & liquidity for large trades.	**De** se ar
Ecosystem & Tech	**Supported Chains** & Monthly Active Wallets	Diverse chains & an active wallet base signal robustness.	**Ac** to pr
Long-Term Trends	**Monthly Traders (MAU)** & **Net Inflows/Outflows**	Steady MAU growth & positive net inflows show strong fundamentals.	**Su** Se fr

🛠️ The Analyst's Toolkit: Python Libraries

Here's the core Python tech stack you'll use for your DeFi EDA.

For Getting Raw On-Chain Data

- `web3.py` : The de facto standard for interacting with Ethereum nodes. Essential for getting raw block and transaction data.
- **Protocol SDKs/APIs**: Simplify data access:
  - **1inch**: Use their Python wrapper `1inch.py` for swap and price data, or the `History API` for transaction analysis.

history API for transaction analysis.

- **CowSwap**: The `cowdao_cowpy` SDK is specifically built for Python developers. The API offers endpoints like `solvable_orders` to get the order book.
- **ParaSwap**: Use the `paraswap-python-sdk` for their API.

- **The Graph**: A decentralized querying protocol. Write GraphQL queries to efficiently access aggregated smart contract data from supported DEXs.

For Data Processing & Analysis

- `pandas` : Use DataFrames for structured data (e.g., time series of daily volumes) to easily filter, group, merge, and aggregate.
- `NumPy` : For efficient numerical operations (e.g., calculating moving averages).

For Visualization

- `matplotlib` : For fine-grained control and wide variety of plots, like a line chart for market share evolution.
- `seaborn` : Built on `matplotlib` , offers high-level interfaces and better defaults for statistical plots (e.g., bar charts comparing slippage).
- `plotly` : For interactive visualizations (like time-series volume charts) that allow zooming.

📊 Putting It All Together: A Practical Example with `matplotlib`

This script fetches hypothetical data to compare the market share of 1inch, CowSwap, and ParaSwap.

```python
import matplotlib.pyplot as plt
import numpy as np

# --- 1. FETCH YOUR DATA (e.g., from APIs, The Graph, etc.) ---
# In a real scenario, you would replace this mock data with your fetched values
protocols = ['1inch', 'CowSwap', 'ParaSwap']
# Example data based on market share trends
# Note: Market shares are dynamic & change over time; see research for latest stats
market_shares = [15, 20, 12] # Percentages for illustrative purposes only
```

```
market_shares = [15, 30, 12] # Percentages for illustrative purposes only

# --- 2. CREATE THE VISUALIZATION (e.g., a Bar Chart) ---
# Create figure and a single subplot
fig, ax = plt.subplots(figsize=(10, 6))

# Colors
colors = ['#4C72B0', '#55A868', '#C44E52']

# Create bars with custom colors
bars = ax.bar(protocols, market_shares, color=colors, edgecolor='black', linewidth=1.2)

# --- 3. CUSTOMIZE AND ANNOTATE ---
# Add value labels on top of each bar
for bar in bars:
    height = bar.get_height()
    ax.text(bar.get_x() + bar.get_width()/2., height + 0.5,
            f'{height}%', ha='center', va='bottom', fontsize=12, fontweight='bold')

# Title and labels
ax.set_title('DEX Aggregator Market Share (Illustrative)', fontsize=16, pad=20)
ax.set_ylabel('Market Share (%)', fontsize=12)
ax.set_xlabel('Protocol', fontsize=12)

# Add a grid for easier readability
ax.yaxis.grid(True, linestyle='--', alpha=0.7)
ax.set_axisbelow(True) # Put grid behind bars

# Optional: Add a footnote with the source of your data
plt.figtext(0.99, 0.01, 'Data source: [Insert your data source, e.g., Dune Analytics quer
y]',
            horizontalalignment='right', fontsize=9, color='gray')

# --- 4. DISPLAY THE CHART ---
plt.tight_layout() # Adjust layout to prevent clipping
plt.show()
```

> *Note: The market share data used in this chart is illustrative. In a real-world analysis, you would need to query market data to get the accurate numbers for your chosen timeframe.*

This will produce a bar chart that clearly visualizes the market share of each protocol, allowing you to compare them at a glance.

allowing you to compare them at a glance.

This should give you a solid foundation to start your EDA. Comparing these aggregators will reveal the unique strengths of each in a fascinating market. Once you've built your analysis, you'll be able to see the data-backed stories of how these protocols are competing and evolving. Good luck with your project! If you run into any specific issues while coding, feel free to ask.

76 web pages

I want to use Etherscan to analyze the 1INCH ERC-20 token on-chain. what should I look at to understand how this token is being used, like who is moving it how much, and how often? what does the transfer activity actually tell me about the protocol? show me how to fetch token transfer data with the Etherscan API in Python and then how to plot the transfer size distribution and daily volume trend

Thought for 9 seconds

The user wants to analyze the 1INCH token using Etherscan. They want to know what metrics to look at to understand usage, who is moving it, how much, and how often, and what transfer activity reveals about the protocol. They also want a Python example to fetch transfer data via Etherscan API and plot transfer size distribution and daily volume trend.

I need to search for resources. I'll search for Etherscan API documentation, 1INCH token contract address, and Python examples for fetching ERC-20 transfer events. I'll also look for metrics and analysis guides.

Found 55 web pages

The search results for the Etherscan API Python tutorial and the token contract address were not very specific. I need to refine my search to find the correct 1INCH token contract address and a direct Python example for fetching transfer events.

Found 30 web pages

The search results for "getTokenTransferEvents" and "ERC20" "token transfer" "Etherscan" python api were not very helpful. I need to directly use the Etherscan API. I'll search for the API documentation.

Found 10 web pages

I need to provide a comprehensive answer. I'll structure it with an introduction, key metrics to

analyze, API integration, visualizations, and a summary. I'll need to cite relevant sources for the metrics, the contract address, the API usage, and the Python code. I'll also need to explain the logic behind each metric. Let's open some of the relevant links to gather detailed information.

Get ERC20 Token Transfers by Address - Etherscan ↗

Track Smart Money On-Chain Without Paid Tools: My Python Guide for Crypto Traders ↗

How to analyze token flows with Dune ↗ 1INCH Token ↗ View All

I have gathered several key pieces of information. The 1INCH token contract address is 0x111111111117dc0aa78b770fa6a738034120c302. The Etherscan API documentation provides the endpoint for token transfers. I have also found a Python script example. I will now structure the answer with an introduction, key metrics and their logic, how to fetch transfer events, how to plot transfer size distribution and daily volume trend, and a conclusion. I'll need to cite the sources appropriately. Now I will formulate the answer.

Analyzing the **transfer activity of a protocol's native token** offers a window into how a decentralized project is actually used. By examining who is moving the token, how often, and in what amounts, you can uncover unique behavioral patterns that set protocols apart from one another.

Before showing you the `Python` code, it's helpful to understand the specific narrative behind the `1INCH` token and what its transfer data reveals.

🔎 The Unique Function of the 1INCH Token

Unlike a simple utility token, the `1INCH` token is central to the ecosystem's security and governance. It's designed to ensure the protocol can remain permissionless, protect its development ecosystem, and provide funds to reward participation in its governance through staking. When you observe the token's transfer activity, you're effectively seeing these ecosystem mechanics in action.

Its total fixed supply is **1,500,000,000** 1INCH [14]. This is a crucial number to keep in mind as it puts the size of the `value` column in your data into perspective.

📊 From On-Chain Data to Actionable Insights

When you fetch the transfer data, here's how to interpret the patterns in the `from` and `to` columns.

Data Attribute	What to Look For	What It Reveals
Who (`from` , `to`)	**Exchanges vs. Private Wallets**: A transfer from a known exchange CEX wallet to an unknown one could signal **accumulation** (buying). The reverse, to a CEX, suggests potential **distribution** (selling) [21] .	**Market Sentiment:** It's the classic supply-and-demand story playing out on-chain.
	Protocol Contracts: Frequent interactions with the `st1INCH` contract address are a direct indicator of **staking activity**	**Ecosystem Health:** High staking activity points to a committed user base contributing to network security.
	Whale Clusters: Grouping addresses by their total transfer volume and associating them can help you spot patterns of institutional behavior that might precede market moves [32] .	**Whale Activity:** Understanding their position can help you anticipate potential shifts in market dynamics.
How Much (`value`)	**Small, Frequent Transfers**: This is classic **retail trading** or automated activities, like yield farming rewards.	**User Engagement:** A high volume of small transactions typically signals a diverse, organic user base [21] .
	Infrequent, Large Transfers: These are your **whale movements** and can be a precursor to significant price action [21] .	**Liquidity & Pressure:** Massive, sudden transfers can signal an incoming wave of either buying or selling pressure.
	Daily Active Addresses (DAU): Tracking the number of	**Token Utility:** A spike in active addresses suggests a specific

How Often (`timeStamp`)	distinct addresses sending or receiving tokens each day provides a direct measure of the token's **velocity**.	event—like a new staking reward program—successfully drove user engagement.

🐍 Python Script: Fetch, Analyze & Visualize

Now, let's get your hands dirty with the Python code. This script will fetch the transfer data, process it, and generate the visualizations you need.

1. Setup Your Environment and API

First, you'll need to install the required libraries and have your Etherscan API key ready.

```bash
pip install requests pandas matplotlib seaborn
```

Then, you can begin scripting.

```python
import requests
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
from datetime import datetime, timedelta

# --- Configuration ---
ETHERSCAN_API_KEY = "YOUR_API_KEY"  # Get yours from etherscan.io
TOKEN_CONTRACT = "0x111111111117dc0aa78b770fa6a738034120c302" # 1INCH token address
# --- End Configuration ---
```

2. Fetch All Token Transfer Events

The Etherscan API's `tokentx` endpoint is designed specifically for this purpose[75]. This function will handle the pagination for you.

```python
def fetch_all_token_transfers(contract_address, api_key):
```

```python
def fetch_all_token_transfers(contract_address, api_key):
    """
    Fetches all ERC-20 token transfer events for a given contract address.
    Handles pagination automatically.
    """
    url = "https://api.etherscan.io/api"
    all_transfers = []
    page = 1
    offset = 10000  # Max records per page

    while True:
        params = {
            "module": "account",
            "action": "tokentx",
            "contractaddress": contract_address,
            "address": contract_address,
            "page": page,
            "offset": offset,
            "sort": "asc",
            "apikey": api_key,
        }
        response = requests.get(url, params=params)
        data = response.json()

        if data["status"] != "1":
            break  # No more data or an error occurred

        transfers = data["result"]
        if not transfers:
            break

        all_transfers.extend(transfers)
        print(f"Fetched page {page}, total transfers so far: {len(all_transfers)}")
        page += 1

    return pd.DataFrame(all_transfers)
```

3. Process the Data for Analysis

Once you have the raw data, you'll need to clean it up and calculate metrics for your visualizations.

```python
```

```
# Fetch the data
df = fetch_all_token_transfers(TOKEN_CONTRACT, ETHERSCAN_API_KEY)

if df.empty:
    print("No transfer data found. Check your contract address and API key.")
else:
    # Convert data types
    df["value"] = pd.to_numeric(df["value"]) / 10**18  # Convert from wei
    df["timestamp"] = pd.to_datetime(df["timeStamp"], unit="s")
    df["date"] = df["timestamp"].dt.date

    print(f"Total transfers fetched: {len(df)}")
    print(df.head())
```

4. Plot 1: Transfer Size Distribution (Histogram)

This plot will reveal the "retail vs. whale" dynamic we discussed earlier.

```python
    # Create a new figure
    plt.figure(figsize=(12, 6))

    # Filter out very large outliers for a clearer view (e.g., transfers > 1,000,000 1INCH)
    plot_df = df[df["value"] <= 1000000]

    # Create the histogram with a log scale for x-axis
    sns.histplot(plot_df["value"], bins=50, log_scale=True, color='skyblue', edgecolor='black')

    # Labeling and formatting
    plt.title("Distribution of 1INCH Transfer Sizes (Log Scale)", fontsize=16, pad=15)
    plt.xlabel("Transfer Size (1INCH)", fontsize=12)
    plt.ylabel("Frequency (Log Scale)", fontsize=12)
    plt.grid(axis='y', alpha=0.5)

    plt.tight_layout()
    plt.show()
```

5. Plot 2: Daily Transfer Volume Trend (Line Plot)

This plot is your dashboard for overall network momentum.

python

```python
# --- Prepare Data for Daily Volume Trend ---
# Group by date and sum the transfer values
daily_volume = df.groupby("date")["value"].sum().reset_index()

# Calculate 7-day moving average to smooth out noise
daily_volume["7d_MA"] = daily_volume["value"].rolling(window=7, min_periods=1).mean()

# --- Create Plot ---
plt.figure(figsize=(14, 7))

# Plot daily volume as bars
plt.bar(daily_volume["date"], daily_volume["value"],
        width=0.8, color="lightcoral", alpha=0.6, label="Daily Transfer Volume")

# Plot moving average as a line
plt.plot(daily_volume["date"], daily_volume["7d_MA"],
         color="darkred", linewidth=2, label="7-Day Moving Average")

# Labeling and formatting
plt.title("Daily 1INCH Transfer Volume on Ethereum", fontsize=16, pad=15)
plt.xlabel("Date", fontsize=12)
plt.ylabel("Volume (1INCH)", fontsize=12)
plt.legend()
plt.grid(axis='y', alpha=0.3)

# Format the x-axis to avoid cluttering the date labels
plt.xticks(rotation=45)
plt.tight_layout()
plt.show()
```

✅ Final Analysis Checklist

Once you have your data and plots ready, use this checklist to build a comprehensive analysis:

- **Build your foundation**: Ensure you have the correct contract address and API key. The Etherscan API free tier generally allows 5 calls per second, which is usually sufficient

for this type of analysis[32].

- **Calculate key metrics**: Go beyond total volume. Compute **daily active addresses**, **average transfer size**, and **transfer velocity** (volume / token supply) to get a complete picture of activity[21].
- **Identify exchange interactions**: Compile a list of known exchange deposit addresses to categorize `to` addresses and measure net exchange flows[32]. Cross-reference net flows with your volume trend to see if large holders are accumulating or distributing.
- **Correlate with events**: Overlay significant dates on your volume plot (e.g., major protocol upgrades, staking program launches) to see how on-chain activity responds to real-world news.

By following this guide, you'll be able to move past basic price charts and gain a far more insightful understanding of the 1INCH protocol. Good luck with your EDA, and feel free to ask if you have any other questions as you work through it.

89 web pages

I want to use The Graph to pull historical data about 1inch. I found a subgraph for the 1inch airdrop that tracks all Claimed events. what does airdrop distribution data tell me about a DeFi protocol?
why does it matter if tokens were distributed evenly or concentrated in a few wallets?
show me how to query a subgraph with Python using paginated GraphQL requests,
and then how to visualize the distribution (like a histogram) so I can see if it was fair or nott

Thought for 16 seconds

The user wants to analyze 1inch airdrop data using The Graph subgraph. I need to explain what airdrop distribution data reveals about a DeFi protocol, why distribution matters, and provide a Python script with paginated GraphQL queries and a histogram visualization. I need to search for the specific subgraph and related information.

Found 48 web pages

The search results for the subgraph didn't directly find the specific 1inch airdrop subgraph. I'll need to search more specifically. The search results for airdrop distribution analysis provide some relevant links, including an analysis by Flipside Crypto and a Chinese article. The search results

relevant links, including an analysis by Flipside Crypto and a Chinese article. The search results for pagination provide general information. I'll need to provide Python code for paginated GraphQL requests. The search results for histogram visualization include a tool called "Airdrop Assist" that might be useful, but I need to find more specific examples. I should also search for "1inch airdrop subgraph GraphQL schema" to understand the data structure.

Found 9 web pages

The search results didn't find the specific subgraph. I'll try searching for "1inch airdrop subgraph thegraph".

Found 9 web pages

The search results didn't find the specific subgraph. It's possible the subgraph is not publicly listed or is behind a specific URL. I might need to guide the user to find the subgraph URL themselves. However, the user says they "found a subgraph for the 1inch airdrop that tracks all Claimed events". That suggests they might have access to it. I can still provide the Python code for paginated queries, assuming they have the endpoint URL and the schema. I'll need to explain the significance of airdrop distribution. Let me open the Flipside Crypto analysis and the Chinese article for more detailed insights.

Read 2 pages Airdrop Analysis by Flipside Crypto: FEI, UNI and 1inch
「空投」是最好的代币分发机制吗?

The article mentions that the 1inch airdrop distributed tokens to about 55,000 addresses, totaling 90 million tokens, which accounted for 6% of the total supply. It also mentions that it might have created the biggest wealth gap among the four major airdrops. This information is useful for explaining the significance of distribution. I'll also need to find a source for the subgraph URL. I'll search for "1inch airdrop subgraph graphql endpoint".

Found 10 web pages

The search results for the subgraph endpoint were not helpful. It's likely that the user has access to a specific subgraph URL, perhaps from a Dune Analytics page or a custom deployment. I can still provide the Python code for paginated queries, assuming they have the endpoint URL. I'll also need to explain the significance of airdrop distribution. The Flipside analysis provides useful insights: nearly 40% of tokens were swapped or transferred to a CEX within 24 hours, and after 90 days, only 36.3% were kept. This indicates that many recipients sold quickly, which could have impacted the token price. The Chinese article mentions that the 1inch airdrop might have created the biggest wealth gap among the four major airdrops, with some addresses receiving much more than others. This highlights the importance of distribution fairness. I'll also need to explain how to query a subgraph with pagination. The open source documentation for GraphQL pagination suggests using `first` and `skip` parameters. I'll provide a Python script that uses the `requests` library to send POST requests with a GraphQL query, and then loops with `skip` to paginate

> through all results. I'll also provide an example of how to visualize the distribution as a histogram using `matplotlib` or `seaborn`. Now, I need to structure a comprehensive answer.

Analyzing a DeFi airdrop's on-chain data isn't just about auditing a list of winners—it's a powerful EDA technique for decoding a protocol's philosophy, tokenomics, and the actual behavior of its early community. Your decision to fetch `Claimed` events using The Graph is a data-driven approach.

The Graph is an indexing protocol that makes this possible. Developers define a "subgraph" to listen for specific smart contract events (like a token being claimed), index the data, and serve it via a GraphQL API, saving you from the complexity of parsing raw blockchain logs.

Here is a practical guide to performing this analysis, from understanding its importance to fetching and visualizing the data.

🤔 Why Airdrop Analysis Matters: More Than Just Free Tokens

Airdrop distribution is often an early snapshot of a protocol's future community and tokenomics. Here is what the data can reveal:

- **Fair Launch vs. Sybil Vulnerability**: Whether tokens were truly distributed to a broad, active user base or gamed by "sybil attackers" who control many wallets. A core story of the 1inch airdrop was the significant "wealth gap" it created, with a small number of addresses receiving an enormous share of the value compared to the majority [12].
- **Initial Sell Pressure & Community Retention**: Analyzing the initial movements of claimed tokens provides a clear proxy for community sentiment. For 1INCH, data shows nearly 40% of tokens were swapped or sent to centralized exchanges **within 24 hours** of being claimed. This rate jumped to nearly 50% within a week [11], suggesting that a significant portion of the initial "community" was motivated by short-term profit-taking rather than long-term participation.

⚖️ The Importance of a Fair Distribution: Initial vs. Long-Term Health

The "evenness" of the distribution—whether the tokens are concentrated in a few wallets or spread widely—is arguably the most critical metric you can analyze.

- **Why it Matters**: A highly concentrated airdrop (a "heavy-tail" distribution) creates a precarious foundation. A few large holders can exert outsized influence on governance votes, and if they decide to sell, they can cause massive price volatility [1][2]. Conversely, a wide and even distribution is a vote of confidence in the protocol's long-term vision, creating a robust, decentralized base of small stakeholders [1][2].

The Python Analyst's Toolkit: Fetching Claim Data via The Graph

The Graph's API is designed for efficient, paginated queries. The key is using GraphQL variables, with `first` to limit results and `skip` to move through the dataset.

Here is a Python script to query a subgraph, fetch all `Claimed` events, and load the data into a pandas DataFrame.

```python
import requests
import pandas as pd
import time

# --- 1. Configuration ---
# !!! IMPORTANT: You need the specific API endpoint for the 1inch airdrop subgraph you fo
und !!!
# It will look something like this:
SUBGRAPH_URL = "https://api.thegraph.com/subgraphs/name/your-username/1inch-airdrop"

# --- 2. Define the GraphQL Query ---
def create_query(first, skip):
    return """
    {
      claimeds(
        first: %d,
        skip: %d,
        orderBy: blockNumber,
        orderDirection: asc
      ) {
        id
        user
        amount
        blockNumber
        transactionHash
```

```
      }
    }
    """ % (first, skip)

# --- 3. Paginated Fetch ---
def fetch_all_claim_events():
    all_claims = []
    skip = 0
    first = 1000 # Max items per request, safe for The Graph
    has_more = True

    while has_more:
        query = create_query(first, skip)
        response = requests.post(SUBGRAPH_URL, json={'query': query})

        if response.status_code == 200:
            data = response.json()
            claims = data.get('data', {}).get('claimeds', [])

            if not claims:
                has_more = False
            else:
                all_claims.extend(claims)
                print(f"Fetched {len(claims)} records, total so far: {len(all_claims)}")
                skip += first
                time.sleep(0.2) # Be polite to the API
        else:
            print(f"Error {response.status_code}: {response.text}")
            has_more = False

    return pd.DataFrame(all_claims)

# --- 4. Execute and Analyze ---
df = fetch_all_claim_events()

if not df.empty:
    # Convert 'amount' from string/wei to a human-readable number
    # The divisor (e.g., 10**18) depends on the token's decimals. 1INCH has 18.
    df['amount'] = df['amount'].astype(float) / 10**18

    print(df.head())
    print(f"\nTotal claims fetched: {len(df)}")
else:
    print("No claim data found.")
```

📊 Visualizing "Fairness": The Gini Coefficient & Histogram

Raw numbers can be deceptive, but a histogram makes the distribution of wealth instantly clear. A "fair" distribution will show a dense cluster of small claims. A "unfair" distribution will show a long "tail" of large claims. To measure this more precisely, you can also calculate the Gini coefficient.

The Code

```python
import matplotlib.pyplot as plt
import seaborn as sns
import numpy as np

def analyze_distribution(df, token_symbol="1INCH"):
    # --- Prepare Data ---
    # Filter out zeros or very small values for a cleaner plot
    amounts = df[df['amount'] > 0]['amount']

    # --- Create the Plot ---
    fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(15, 6))

    # 1. Histogram
    # Log scale on x-axis is crucial to handle the wide range of claim sizes
    bins = np.logspace(np.log10(amounts.min()), np.log10(amounts.max()), 50)
    ax1.hist(amounts, bins=bins, alpha=0.7, color='skyblue', edgecolor='black')
    ax1.set_xscale('log')
    ax1.set_xlabel(f'Claimed Amount ({token_symbol})', fontsize=12)
    ax1.set_ylabel('Number of Addresses', fontsize=12)
    ax1.set_title('Distribution of Airdrop Claim Sizes', fontsize=14)
    ax1.grid(True, axis='y', linestyle='--', alpha=0.5)

    # 2. Cumulative Distribution
    sorted_amounts = np.sort(amounts)
    cumulative_share = np.cumsum(sorted_amounts) / sorted_amounts.sum()
    n = len(sorted_amounts)
    ax2.plot(np.arange(n) / n, cumulative_share, label='Observed', color='darkblue')

    # --- Gini Coefficient Calculation ---
```

```
    # The Gini coefficient measures statistical dispersion. 0 = perfect equality, 1 = tot
al inequality.
    # Based on the Lorenz curve
    area_under_curve = np.trapz(cumulative_share, dx=1/n)
    gini_coefficient = 1 - 2 * area_under_curve

    ax2.plot([0, 1], [0, 1], '--', label='Perfect Equality', color='gray')
    ax2.set_xlabel('Cumulative Share of Addresses', fontsize=12)
    ax2.set_ylabel('Cumulative Share of Tokens', fontsize=12)
    ax2.set_title(f'Lorenz Curve (Gini: {gini_coefficient:.3f})', fontsize=14)
    ax2.legend()
    ax2.grid(True, linestyle='--', alpha=0.5)

    plt.tight_layout()
    plt.show()

if not df.empty:
    analyze_distribution(df)
```

This will produce a two-panel visualization. The left panel is a histogram showing the distribution of claim sizes on a log scale, allowing you to see both the many small claims and the few very large ones. The right panel is a Lorenz curve, providing a formal
A Lorenz curve plots the cumulative share of the total claimed tokens against the cumulative share of the addresses claiming them. A Gini coefficient (e.g., `0.6` or `0.7`) is a strong sign of a "heavy-tail" distribution. For the 1INCH airdrop, we would likely see a Gini coefficient indicating a significant level of inequality, which would confirm the observed "wealth gap" where a few addresses received most of the value [12].

This combination of a revealing metric (the Gini coefficient) and a clear visual (the histogram) transforms your EDA from just "tracking claims" into a rigorous analysis of the protocol's foundational tokenomics.

If you'd like to take this historical analysis further, we can look at what happened next—like analyzing the claiming patterns or how quickly tokens moved to exchanges. Just let me know what interests you.

I want to use DeFiLlama to compare 1inch against CowSwap and ParaSwap by trading volume, what does DEX aggregator volume actually

ParaSwap by trading volume, what does DEX aggregator volume actually measure, and why is it a good or bad proxy
for how healthy a protocol is? What should I look for when comparing competitors?
show me how to call the DeFiLlama REST API in Python to get historical daily volume,
and then how to plot a volume comparison and market share chart over time using plotly

Thought for 23 seconds

The user wants to learn about using DeFiLlama to compare DEX aggregators (1inch, CowSwap, ParaSwap) by trading volume. They want to understand what volume measures, its pros and cons as a health proxy, what to look for in comparisons, and how to fetch and visualize data via Python and Plotly. I need to follow the search plan outlined in the hint. I will start with Round One operations.

Found 50 web pages

The search results have provided some relevant information, but many results are not directly about the DeFiLlama API. I need to open the most promising ones to gather details. I will open result 0 from the first search, result 0 from the second search, result 0 from the third search, result 0 from the fourth search, and result 0 from the fifth search.

Ethereum DEX Aggregator Market Grows More Competitive: Guest Post by Kanalcoin | CoinMarketCap

DefiLlama Scraper API in Python · Apify

The search results provide some relevant information, but not all of it is directly about the DeFiLlama API. I need to open the most promising ones to gather details. I've opened result 0 from the first search, result 0 from the second search, result 0 from the third search, result 0 from the fourth search, and result 0 from the fifth search. The results show some documentation and examples, but I need to find the actual API endpoints for historical volume data. Perhaps I can search for "defillama api historical volume" or "defillama api endpoints". I'll also need to find the slugs for the protocols. I'll search for "defillama api volume 1inch" and "defillama api cowswap".

Found 36 web pages

The search results for the API endpoints are not very helpful. Perhaps I can find the API documentation directly. I'll search for "defillama api docs".

documentation directly. I'll search for "defillama api docs".

Found 10 web pages

Result 1 seems to point to "https://defillama.com/docs/api". I'll open that.

Read 1 page GitHub - jafark92/defillamaAPI: API Collection of DefiLlama - Unofficial · GitHub

The page mentions "https://defillama.com/docs/api". I'll open that.

Read 1 page API Docs

The API docs page seems to cover TVL, but I need volume data for aggregators. I'll search within the page for "aggregator".

No related content found

Maybe the aggregator volume data is under a different section. I'll search for "volume".

No related content found

The API docs page might not be fully loaded in the text view. Perhaps there is a separate endpoint for aggregator volume. I recall that DeFiLlama has an endpoint like `/overview/aggregators`. I'll try to access that directly.

Read 1 page api.llama.fi

The response seems to be a list of historical total aggregator volume data. But I need volume per protocol. Perhaps there is an endpoint like `/overview/aggregators/{chain}` or something. I'll search for "1inch" in the page.

No related content found

So the `/overview/aggregators` endpoint might only return total volume across all aggregators. For protocol-specific volume, I might need to use the `/summary/aggregators/{slug}` endpoint. I'll try to find the slugs for 1inch, CowSwap, and ParaSwap. I can search for "1inch defillama slug".

Found 2 web pages

Result 1 is a page for 1inch Network. I'll open it.

Read 1 page 1inch Network

This page shows some volume metrics, but I need historical daily volume. Maybe there is an API endpoint for that. I recall that DeFiLlama has a `/summary/aggregators/{slug}` endpoint. I'll try to guess the slugs. For 1inch, the slug might be "1inch-network". For CowSwap, it might be "cowswap". For ParaSwap, it might be "paraswap". I'll test by trying to open the API endpoints.

Read 3 pages api.llama.fi, api.llama.fi, api.llama.fi

Read 3 pages api.llama.fi api.llama.fi api.llama.fi

> The endpoint for paraSwap seems to have rebranded to Velora. I need to find the correct slug for ParaSwap. Maybe it's "paraswap" but the response shows "Velora". Perhaps the original ParaSwap data is still available under "paraswap". I'll try "paraswap" but use the correct slug format. Actually, the response for "paraswap" shows "Velora", but the historical data might still be valid. I'll proceed with that.
>
> Now I need to find the historical daily volume data. The `totalDataChart` field in the response seems to contain daily volume data (timestamp, volume). I can use that. I'll need to extract that data for each protocol.
>
> Now I need to provide the user with a Python script to fetch and plot the data. I'll also need to explain the volume metric and its pros and cons. I'll structure the answer accordingly.
>
> I'll now start writing the final answer.

Excellent question. Comparing DEX aggregators by volume is a cornerstone of any meaningful competitive analysis, but it's also a metric that's easily misunderstood. Let's break down what volume actually tells you and then get into the practical steps of retrieving and visualizing it.

🤔 What DEX Aggregator Volume Measures (And Its Limitations)

DEX Aggregator Volume is the total USD value of all spot token swaps routed through a protocol like 1inch, CowSwap, or ParaSwap. It's the aggregated value from thousands of individual trades. DeFiLlama collects this data from each protocol via open-source "dimension adapters" that index on-chain swap events [11].

While volume is a powerful indicator of market activity and user adoption, it has notable limitations:

✅ Why It's a Good Proxy for Health	❌ Why It's a Flawed Metric
User Adoption: High volume = more people are using the protocol.	**Wash Trading / Sybils:** Can be artificially inflated.
Liquidity & Efficiency: High volume usually means users get better execution (lower slippage) due to more activity passing through the router.	**Volume ≠ Revenue:** High volume doesn't necessarily mean the protocol is profitable; fees and costs matter.

Market Leadership: Volume share indicates competitive standing and brand trust.	**"Gaming" the Metric:** Protocols can incentivize volume with token rewards, creating temporary spikes.
Network Effects: More volume can attract more liquidity sources, improving the product further.	**Quality vs. Quantity:** Many small trades might look good but don't necessarily indicate deep liquidity for large trades.

📈 What to Look For When Comparing Competitors

Beyond just raw volume, a sophisticated analysis focuses on:

- **Market Share Dynamics**: Which aggregator is gaining or losing share? For example, in early 2025, 1inch's lead narrowed significantly as CoW Swap surged to a 27.21% share vs 1inch's 28.4%[33]. This highlights shifting user preferences and competitive pressures.
- **Multi-Chain Footprint**: Check which chains each protocol supports. 1inch boasts support for 21 chains, while CowSwap focuses on Ethereum, Gnosis, and Arbitrum, and ParaSwap covers 14[24]. A protocol's multi-chain strategy is key to long-term growth.
- **Volume to TVL Ratio**: This metric (Volume divided by Total Value Locked) shows the capital efficiency of the protocol. A higher ratio indicates that a protocol is generating more trading activity per dollar of value locked, which is a sign of a healthy, active user base.
- **Correlation with User Numbers**: Is volume growing because of more users, or just the same users trading more? Tracking active traders alongside volume reveals the true nature of the growth.

🐍 Fetching and Visualizing Volume with Python & Plotly

Now, let's get to the code. We'll use DeFiLlama's public API to fetch the historical daily volume for 1inch, CowSwap, and ParaSwap and then visualize the data with Plotly.

Step 1: Install Required Libraries

bash

```
pip install requests pandas plotly
```

Step 2: Fetch Data from DeFiLlama

The key endpoint is `https://api.llama.fi/summary/aggregators/{slug}` . Based on our research, the slugs are:

- 1inch: `1inch-network`
- CowSwap: `cowswap`
- ParaSwap: `paraswap`

Let's write a function to fetch and parse the data.

python

```python
import requests
import pandas as pd
import time

def fetch_aggregator_volume(slug):
    """Fetch historical daily volume for a given aggregator slug from DeFiLlama."""
    url = f"https://api.llama.fi/summary/aggregators/{slug}"

    try:
        response = requests.get(url, timeout=30)
        response.raise_for_status()
        data = response.json()

        # Extract the historical volume data from the API response
        # 'totalDataChart' contains list of [timestamp, volume] pairs
        raw_data = data.get('totalDataChart', [])

        if not raw_data:
            print(f"⚠️ No data found for slug: {slug}")
            return pd.DataFrame()

        df = pd.DataFrame(raw_data, columns=['timestamp', slug])
        df['timestamp'] = pd.to_datetime(df['timestamp'], unit='s')
        df.set_index('timestamp', inplace=True)
```

```
        # DeFiLlama returns volume in USD; no conversion needed
        print(f"✅ Fetched {len(df)} days of data for {slug}")
        return df

    except Exception as e:
        print(f"❌ Error fetching {slug}: {e}")
        return pd.DataFrame()

# Fetch data for each protocol
protocols_slugs = {
    '1inch': '1inch-network',
    'cowswap': 'cowswap',
    'paraswap': 'paraswap'
}

dataframes = {}
for name, slug in protocols_slugs.items():
    df = fetch_aggregator_volume(slug)
    if not df.empty:
        dataframes[name] = df
    time.sleep(0.2)  # Be polite to the API

# Combine all data into a single DataFrame
combined_df = pd.concat(dataframes.values(), axis=1)
combined_df = combined_df.fillna(0)  # Fill any missing dates with 0

print("\nCombined data preview:")
print(combined_df.head())
print(combined_df.tail())
```

Step 3: Plot the Volume Comparison with Plotly

Now, let's create an interactive line chart to visualize the volume trends.

```python
import plotly.graph_objects as go
import plotly.express as px

# Create the figure
fig = go.Figure()

# Add a trace for each protocol
```

```
for protocol in combined_df.columns:
    fig.add_trace(go.Scatter(
        x=combined_df.index,
        y=combined_df[protocol],
        name=protocol.capitalize(),
        mode='lines',
        line=dict(width=2)
    ))

# Update layout for better visualization
fig.update_layout(
    title={
        'text': 'Daily Trading Volume: 1inch vs CowSwap vs ParaSwap',
        'x': 0.5,
        'xanchor': 'center',
        'font': {'size': 20}
    },
    xaxis_title='Date',
    yaxis_title='Volume (USD)',
    legend_title='Protocol',
    template='plotly_white',
    hovermode='x unified',
    width=1000,
    height=600
)

# Add a range slider for interactivity
fig.update_xaxes(rangeslider_visible=True)

# Show the plot
fig.show()
```

This code will produce an interactive chart where you can:

- Hover over lines to see exact values
- Zoom in on specific time periods
- Toggle protocols on and off
- Use the range slider to focus on different date ranges

Step 4: Calculate and Plot Market Share

Market share adds another critical dimension to your analysis. Here's a quick way to

Market share adds another critical dimension to your analysis. Here's a quick way to calculate and visualize it.

```python
# Calculate total volume across aggregators per day
combined_df['total_volume'] = combined_df.sum(axis=1)

# Calculate market share for each protocol
market_share = combined_df.div(combined_df['total_volume'], axis=0) * 100
market_share = market_share.drop('total_volume', axis=1)  # Remove the total column

# Plot market share as an area chart
fig = go.Figure()

for protocol in market_share.columns:
    fig.add_trace(go.Scatter(
        x=market_share.index,
        y=market_share[protocol],
        name=protocol.capitalize(),
        mode='lines',
        stackgroup='one',  # This creates the area chart effect
        line=dict(width=1),
        fill='tonexty'
    ))

fig.update_layout(
    title={
        'text': 'DEX Aggregator Market Share Over Time',
        'x': 0.5,
        'font': {'size': 20}
    },
    xaxis_title='Date',
    yaxis_title='Market Share (%)',
    legend_title='Protocol',
    template='plotly_white',
    hovermode='x unified',
    width=1000,
    height=600
)

fig.show()
```

This area chart will clearly show how the market share pie has shifted over time, making

This area chart will clearly show how the market share pie has shifted over time, making it easy to spot trends like CoW Swap's recent gains against 1inch.

✅ Final Analysis Workflow

Here's a suggested workflow for your EDA:

1. **Start with the code above** to fetch and visualize the core volume data.
2. **Identify key periods** where market shares shifted significantly. For example, research what caused CoW Swap's share to jump from ~18% to ~27% over 2024[33].
3. **Layer in other metrics** like fee data, unique users, or multi-chain breakdowns by exploring other DeFiLlama API endpoints, such as `/overview/aggregators` for a top-level market view[1].
4. **Correlate volume with major protocol events** (e.g., token launches, new chain integrations, or major feature releases) to understand causality.

This combination of technical analysis and market context will transform your EDA from a simple data pull into a powerful strategic analysis. Good luck with your project! If you encounter any issues or want to explore further metrics, just let me know.

101 web pages

> I want to use CoinGecko to look at the 1INCH governance token and compare it to the COW token.
> why would I compare protocol tokens even if I'm doing EDA on the protocols themselves?
> what does token price and market cap tell me — and what doesn't it tell me? show me how to fetch historical price, market cap, and volume from the CoinGecko API in Python, then show me how to normalize two tokens to the same starting point (index = 100) so I can compare their 12-month performance on one chart

Thought for 12 seconds

> The user wants to compare the 1INCH and COW governance tokens. I need to explain why token analysis is important for protocol EDA, what token price and market cap reveal and conceal, and provide Python code to fetch historical data from CoinGecko and create a normalized performance chart. I'll need to search for CoinGecko API documentation, token IDs, and relevant

market data. I'll follow the search plan.

Found 54 web pages

The search results for the API documentation and token IDs are in. Now I need to open the relevant documentation pages and the token pages to get the correct IDs and understand the API endpoints.

Read 4 pages Coin Historical Chart Data within Time Range by ID - CoinGecko API
2. Get Historical Data - CoinGecko API
Cena 1inch: aktuálny cenový graf, trhová kapitaliázia a dnešné novinky o 1INCH | CoinGecko
Cow Kurs in US Dollar: COW in USD | CoinGecko

The token IDs are available. For 1INCH, the ID is "1inch". For COW, the page shows "cow" as the ID? The URL suggests the ID might be "cow". I need to confirm. Also, the search results show a page for "cow" but the token appears to be a different "Cow" token. I need to search for "CoW Protocol token CoinGecko ID".

Found 10 web pages

The search result shows the CoinGecko page for "cow-protocol". I should open that.

Read 1 page Add {COW}: {COW PROTOCOL TOKEN} · Issue #175 · 1Hive/default-token-list

So the COW token's CoinGecko ID is likely "cow-protocol". I should verify by opening the page.

Read 1 page CoW Protocol COW Price

Scrolling further.

No related content found

I'll look for "API" instead.

No related content found

The API ID might be in the page source. I'll check the page source.

Read 1 page CoW Protocol COW Price

The page has 106 lines. I'll view the entire page.

Read 1 page CoW Protocol COW Price

The page source doesn't show the API ID. I can use the CoinGecko API's /coins/list endpoint to find the ID. But I can also infer from the URL slug: "cow-protocol" is the ID. I'll assume that. Now, I need to provide the answer. The answer will include explanations of why token analysis is

> important, what price and market cap reveal and conceal, and Python code to fetch historical data and create a normalized index chart. I'll also include a note about the API key and rate limits.

Comparing a protocol's governance token can be just as insightful as comparing its core metrics like volume or user activity. While a token's price and market cap are key indicators, they don't always tell the full story. A normalized performance chart is a great tool for making a fair comparison, especially when tokens start from very different price points.

Let's break down what token metrics can tell you about a protocol's health and walk through a practical approach to get this data from CoinGecko and visualize it side-by-side.

🔍 Why Compare Protocol Tokens for EDA?

Looking at just the **price** and **market cap** of a token can provide an incomplete picture. Paired with the protocol's fundamentals, these metrics become powerful signals:

- **Price**: A high price might reflect genuine market confidence in the protocol's roadmap, or it could be distorted by a small, illiquid circulating supply.
- **Market Cap (Market Capitalization)**: This is calculated as the token's price multiplied by its circulating supply. It gives a sense of the overall value the market assigns to the protocol. While one aggregator might have a much lower market cap, that could represent more opportunity for growth—or simply be due to having a much smaller circulating supply than its competitors[18].

Looking at these metrics together helps you move past potentially misleading signals and start to build a clearer, more strategic understanding of where the protocol sits in the market.

📈 Normalizing Token Performance: Indexing to 100

Since tokens start at different price levels, comparing their raw dollar prices is like comparing apples to oranges. The solution is **indexing**.

The idea is simple: set the price on a chosen start date to a common baseline of **100**. As the price moves, you track the index value to see the percentage change from that

starting point.

- Formula: `(Current Price / Starting Price) * 100`

For example, if Token A goes from $1 to 10$ and Token B from $100 to 250$:

- Token A becomes `($10/$1)*100 = 1,000`
- Token B becomes `($250/$100)*100 = 250`

This shows Token A grew 10x, vastly outperforming Token B's 2.5x, a crucial insight you'd miss by just comparing the raw prices of $10 vs. 250$.

🐍 Python Implementation: Fetching and Plotting with CoinGecko

Here's how to build this analysis in Python. You'll need to install the `requests` and `matplotlib` libraries first (`pip install requests matplotlib`).

1. Setup and Getting Token IDs

First, you need the correct CoinGecko API ID for each token. You can find these on the coin's page on CoinGecko or by using the `/coins/list` endpoint. We'll hardcode them for this example:

```python
import requests
import pandas as pd
import matplotlib.pyplot as plt
from datetime import datetime, timedelta

# Define the tokens with their CoinGecko IDs
# You can find these IDs by searching on CoinGecko or using their /coins/list endpoint
tokens = {
    "1INCH": "1inch",
    "COW Token": "cow-protocol"  # This is the correct ID for the CoW Protocol token
}
```

2. Fetching Historical Data

The CoinGecko API's `/coins/{id}/market_chart/range` endpoint is designed for this task.[2] It returns daily prices for a given time range.

task 2. It returns daily prices for a given time range.

```python
def get_historical_data(token_id, vs_currency='usd', days=365):
    """
    Fetch historical daily price data for a given token from CoinGecko.
    Returns a pandas Series with dates as the index and prices as values.
    """
    # Calculate the 'from' and 'to' timestamps for the API
    to_timestamp = int(datetime.now().timestamp())
    from_timestamp = int((datetime.now() - timedelta(days=days)).timestamp())

    url = f"https://api.coingecko.com/api/v3/coins/{token_id}/market_chart/range"
    params = {
        'vs_currency': vs_currency,
        'from': from_timestamp,
        'to': to_timestamp
    }

    try:
        response = requests.get(url, params=params)
        response.raise_for_status()
        data = response.json()

        # The 'prices' field contains a list of [timestamp, price] pairs
        price_data = data['prices']
        df = pd.DataFrame(price_data, columns=['timestamp', 'price'])
        df['date'] = pd.to_datetime(df['timestamp'], unit='ms')
        df.set_index('date', inplace=True)

        # CoinGecko returns data with automatic granularity:
        # - For periods > 90 days, it returns daily data (00:00 UTC)[reference:6]
        # - This matches our 365-day request perfectly
        return df['price']

    except Exception as e:
        print(f"Error fetching data for {token_id}: {e}")
        return None
```

3. Indexing the Data and Plotting

Once you have the price series, you can apply the indexing formula to create a fair comparative chart.

comparative chart.

```python
# Fetch data for all tokens
price_data = {}
for name, token_id in tokens.items():
    price_series = get_historical_data(token_id, days=365)
    if price_series is not None:
        price_data[name] = price_series

# Combine all price data into one DataFrame
df_prices = pd.DataFrame(price_data)

# Normalize (index to 100) based on the first non-null price
# Fill any forward to handle potential missing values
df_prices = df_prices.fillna(method='ffill')
normalized = df_prices.div(df_prices.iloc[0]) * 100

# Plot the normalized performance
plt.figure(figsize=(12, 6))
for column in normalized.columns:
    plt.plot(normalized.index, normalized[column], label=column)

plt.title('12-Month Normalized Token Performance (Indexed to 100)', fontsize=14)
plt.xlabel('Date', fontsize=12)
plt.ylabel('Normalized Price (Index: Start = 100)', fontsize=12)
plt.legend()
plt.grid(True, linestyle='--', alpha=0.7)
plt.tight_layout()
plt.show()
```

A Note on Rate Limits: The CoinGecko API's free tier has a rate limit of 10-50 calls per minute. This simple script makes just two calls, which is well within the limit for personal analysis.

This approach transforms a simple price chart into a powerful, analytical tool. By comparing the normalized performance of 1INCH and the COW token against each other, you can uncover the subtle but significant competitive and market dynamics that raw numbers often obscure.

If you try this and want to dig deeper into supply dynamics or compare them with a third

aggregator like ParaSwap, feel free to ask.

I want to use Dune Analytics to query on-chain data about multiple DEX aggregators at once, what is Dune and how is it different from calling an API directly? what kind of questions can I answer with Dune that I can't easily answer with Etherscan?
show me how to use the dune-client Python library to fetch results from an existing query
without re-running it. Then show me how to make a stacxked bar chart of weekly volume
by protocol, and a stacked area chart of weekly market share percentages

Thought for 4 seconds

> The user wants to know about Dune Analytics, how it differs from direct API calls, what questions it can answer that Etherscan can't, and how to use the dune-client Python library to fetch existing query results and create visualizations. I need to search for the necessary information.

Found 59 web pages

> The search results provide some information. I need to open the relevant pages to gather more details.

Read 7 pages dex_aggregator.trades on zksync - Dune Docs Dune Analytics: Complete On-Chain Research Guide I BYDFi dune-client Execution & Results - Dune Docs Python - Dune Docs View All

> The search results provide information on Dune Analytics, its differences from Etherscan, the dune-client library, and DEX data tables. I need to synthesize this to answer the user's question. I'll structure the answer with an introduction to Dune, a comparison table, example questions, and then the Python code for fetching data and creating visualizations.

Dune Analytics unlocks a whole new dimension for your DeFi analysis, taking you far beyond what's possible with a block explorer like Etherscan. Let's explore when and why you'd choose Dune over an API for your aggregator EDA, then get right into the Python code you requested.

What is Dune Analytics? The Business Intelligence Layer of

🤔 What is Dune Analytics? The Business Intelligence Layer of Crypto

Think of Etherscan as a data source and Dune as the data warehouse and visualization platform. Here's a breakdown of the key differences:

Feature	Etherscan (via API)	Dune Analytics (via Python Client)
Primary Purpose	Transaction explorer for individual transactions	Data analytics platform for business intelligence
Data Retrieval	Fetched via field-specific API calls	Queried using SQL on pre-indexed, relational tables
Data Model	Atomic, single-fetch records	Unified, cross-chain schema built by the community [40]
Perspective	Single-axis (one transaction)	Multi-dimensional (aggregated trends)
Skill Set	Programming-focused (Python, JS)	SQL-focused (often no-code via existing dashboards)
Cost for EDA	Free tier with rate limits, charges for larger queries	Free tier with community dashboards, Pro for private queries [12]

🤔 Why Choose Dune? The Questions You Can't (Easily) Answer with Etherscan

While Etherscan is perfect for tracking a single wallet or transaction, Dune is a business intelligence tool for blockchain data [12]. Blockchains are transparent, but raw data is unusable [12]. Dune gives you answers to high-level, aggregate questions across multiple protocols, which would be a massive task with an API:

- **Measuring "Intended Trades" vs. "Routing Steps"**: When a user swaps USDC to PEPE, the aggregator might route it through USDC→WETH→PEPE. A simple Etherscan API call to a DEX will record the **two intermediary trades**, making it hard to track the user's original intention. Dune's `dex_aggregator_trades` table condenses this into a

user's original intention. Dune's `dex_aggregator.trades` table condenses this into a **single entry**, capturing the true user intent and final amounts [1]. This is the goldmine for volume analysis.

- **Cross-Protocol Aggregator Market Share**: On Etherscan, you would need to identify and track all contract addresses for 1inch, Paraswap, and CowSwap, then aggregate millions of transactions across them. In Dune, you just query, `SELECT project, SUM(amount_usd) FROM dex_aggregator.trades`, and group by `project`.
- **Time-Series Analysis of User Cohorts**: With Dune's powerful SQL, you can track how many users from last month's airdrop are still active today, a complex query that's far beyond Etherscan's scope.
- **Multi-Chain Aggregator Comparison**: Dune provides a standardized schema across 50+ EVM chains, allowing you to see, for the first time, your aggregators' performance on Arbitrum compared to Polygon in a single query[40].

🐍 Fetching Dune Data with Python (Without Re-Running the Query)

Here's how to use the `dune-client` Python library to get data from an *existing* Dune query using the credit-free `get_latest_result`[31]. We'll use the `dex_aggregator.trades` table as our example dataset and build the requested visualizations in Plotly [1].

1. Setup and Authentication

First, install the library and get your API key (found in your Dune account settings).

```bash
pip install dune-client pandas plotly
```

```python
import os
import pandas as pd
import plotly.graph_objects as go
from dune_client.client import DuneClient

# 1. Initialize the client
# You can set your API key as an env variable 'DUNE_API_KEY'
api_key = "YOUR_DUNE_API_KEY"
```

```
client = DuneClient(api_key=api_key)

# 2. Define the Dune Query ID (this is a placeholder)
# You'll replace this with the ID of your own or a public Dune query.
# For this example, we'll assume you have a query that returns
# weekly volume by project and date.
DUNE_QUERY_ID = 1234567  # <--- Replace with your actual Dune Query ID
```

2. Fetch Results from an Existing Query

We'll use `get_latest_results_dataframe()` to get a pandas DataFrame without consuming credits [31] [30]. This replaces the need for a `run_query()` call which would re-execute the query and cost credits.

```python
# Fetch the latest results as a Pandas DataFrame
# This does not re-run the query; it fetches the last stored result.
print(f"Fetching latest results for Dune Query ID: {DUNE_QUERY_ID}")
try:
    # Use get_latest_results_dataframe for a pandas DataFrame
    # which is great for our next steps.
    df_results = client.get_latest_result_dataframe(DUNE_QUERY_ID)
    print("Data fetched successfully!")
    print(df_results.head())
except Exception as e:
    print(f"An error occurred: {e}")
    print("Ensure the query ID is correct and the query has been executed at least once b
efore.")
```

The `df_results` now contains your data, ready for transformation into the visualizations you requested.

3. Transform Data for Visualizations

The Dune API is powerful, but it returns your query's raw output. To build the charts you requested, a bit of pandas manipulation is typically required. Here's how to structure your data for the charts:

```python
# --- Data for Charts
```

```
# --- Data for Charts ---

# --- A. Data for Stacked Bar Chart (Weekly Volume by Protocol) ---
# We need: 'week_start', 'project', 'weekly_volume'
df_bar_data = df_results.groupby(['week_start', 'project'])['weekly_volume'].sum().reset_
index()
df_bar_pivot = df_bar_data.pivot(index='week_start', columns='project', values='weekly_vo
lume').fillna(0)

# --- B. Data for Stacked Area Chart (Weekly Market Share by Protocol) ---
# First, calculate total volume per week
df_results['total_weekly_volume'] = df_results.groupby('week_start')['weekly_volume'].tra
nsform('sum')
# Then, calculate market share as a percentage
df_results['market_share_pct'] = (df_results['weekly_volume'] / df_results['total_weekly_
volume']) * 100

# Now, reshape the data for the area chart
df_area_data = df_results.groupby(['week_start', 'project'])['market_share_pct'].sum().re
set_index()
df_area_pivot = df_area_data.pivot(index='week_start', columns='project', values='market_
share_pct').fillna(0)
```

4. Create the Visualizations with Plotly

Now let's build the interactive charts you wanted.

Chart 1: Stacked Bar Chart of Weekly Volume by Protocol

```python
# Create the stacked bar chart
fig_bar = go.Figure()

# Add a trace (bar) for each protocol (column) in your pivoted DataFrame
for project in df_bar_pivot.columns:
    fig_bar.add_trace(go.Bar(
        x=df_bar_pivot.index,
        y=df_bar_pivot[project],
        name=project,
        stackgroup='one'  # This creates the "stacked" effect
    ))

# Update the layout for clarity
```

```
# Update the layout for clarity
fig_bar.update_layout(
    title='Weekly DEX Aggregator Volume Breakdown',
    xaxis_title='Week Starting',
    yaxis_title='Total Volume (USD)',
    barmode='stack',  # The "stacked" bar mode
    legend_title='Protocol',
    hovermode='x unified'
)

fig_bar.show()
```

Chart 2: Stacked Area Chart of Weekly Market Share Percentages

```python
# Create the stacked area chart
fig_area = go.Figure()

# Add a trace for each protocol's market share
for project in df_area_pivot.columns:
    fig_area.add_trace(go.Scatter(
        x=df_area_pivot.index,
        y=df_area_pivot[project],
        name=project,
        stackgroup='one', # This makes it a stacked area chart
        groupnorm='percent', # Normalizes each stack to 100%
        fill='tonexty',
        line=dict(width=0.5, color='white')
    ))

fig_area.update_layout(
    title='Weekly DEX Aggregator Market Share Breakdown',
    xaxis_title='Week Starting',
    yaxis_title='Market Share (%)',
    legend_title='Protocol',
    yaxis=dict(tickformat=".0f"), # Formats as whole numbers
    hovermode='x unified'
)

# Ensure the Y-axis goes from 0% to 100%
fig_area.update_yaxes(range=[0, 100])

fig_area.show()
```

```
fig_area.show()
```

✅ Your EDA Workflow Checklist for Dune

1. **Discover and "Fork"**: Use the Dune web UI to search for a dashboard or query that has the base data you need. "Fork" it to your own workspace to see the underlying SQL.
2. **Modify the Query**: Tweak the SQL to ensure it returns exactly the columns you need: `week_start`, `project`, and `weekly_volume`. Run it to confirm the output.
3. **Get the Query ID**: Find the numeric ID in the URL of your modified query (e.g., `dune.com/queries/1234567/...`).
4. **Fetch**: Use the `dune-client` library in Python to pull the results using `get_latest_result_dataframe()`.
5. **Visualize**: Use the provided Plotly templates to create your analysis.

You now have a powerful, reproducible pipeline for pulling large, complex, multi-protocol datasets from Dune and building custom, interactive visualizations directly in Python.

Happy analyzing! If you're interested in exploring other aggregator metrics, feel free to ask.

59 web pages

I now have data from 5 sources: Etherscan, The Graph, DeFiLlama, CoinGecko, and Dune, how do I write a short but meaningful summary of what I found? what is the right way to connect findings across multiple data sources like if DeFiLlama and Dune both say something about 1inch's market position, how do I combine those into one conclusion rather than just listing facts?
write me an example summary and conclusion section for a notebook on 1inch vs CowSwap vs ParaSwap, using made-up but realistic numbers as placeholders iw ill change them alteer by myself

Thought for 1 second

> We need to provide guidance on synthesizing multi-source data into a coherent summary, then give an example summary/conclusion. The user wants a template with realistic placeholder

> numbers. We'll write a concise guide and then the example.

You've done the hard work—now it's time to turn raw numbers into a story. Combining insights from five different data sources is exactly what separates a notebook full of charts from a meaningful analysis. Here's how to write a short but powerful summary and conclusion section.

🧩 Connecting Findings Across Multiple Sources

The right way is to **triangulate**: when two independent sources point to the same trend, you can state it with high confidence. When they disagree, you investigate why (e.g., Dune includes multi-chain volume, DeFiLlama may focus on Ethereum-only).

A simple mental model:

- **DeFiLlama / Dune** → tell you *what happened* (volume, market share)
- **Etherscan / The Graph** → tell you *who did it* (transfer patterns, airdrop distribution)
- **CoinGecko** → tells you *how the market valued it* (price, cap)

Connecting them in one conclusion:

> *"DeFiLlama and Dune both show 1inch losing market share to CowSwap in Q1 2025. Etherscan transfer data confirms that the same period saw large 1INCH outflows to exchanges from a small cluster of addresses—likely the top airdrop recipients identified in The Graph claims. CoinGecko's price underperformance of 1INCH (-34%) vs COW (+12%) over 12 months is consistent with this structural shift in both volume and token holder behavior."*

Now let's put this into a realistic notebook summary and conclusion section.

📓 Example Summary & Conclusion Section

You can copy this directly into your notebook and replace the numbers with your real findings.

```markdown
```

Summary of Findings

We analyzed the competitive landscape of three major DEX aggregators—**1inch**, **CowSwap**, and **ParaSwap**—using five complementary on-chain and market data sources. Below we synthesise the most important patterns.

1. Volume & Market Share (DeFiLlama + Dune)
- **1inch** remains the leader by raw volume (~$2.1B weekly as of April 2026), but its share has eroded from 52% to 38% over the last 12 months.
- **CowSwap** showed the strongest relative growth, tripling its weekly volume to $1.4B and capturing 27% market share (up from 12%).
- **ParaSwap** stayed stable at ~15% share with weekly volume around $0.8B.
- *Triangulation*: Both DeFiLlama and Dune data aligned within 5% after adjusting for Dune's multi-chain inclusion (Arbitrum & Polygon contribute 12% of CowSwap volume, vs. 5% for 1inch).

2. Token Holder Behavior & Airdrop Legacy (Etherscan + The Graph)
- The 1INCH airdrop exhibited high inequality: top 2% of claim addresses received 64% of all distributed tokens (Gini coefficient = 0.71).
- From Etherscan transfer logs, those same addresses (cross-referenced by transaction hashes) moved >80% of their claimed 1INCH to exchanges within 48 hours of the claim.
- For CowSwap (COW token), airdrop claims were more evenly distributed (Gini = 0.43) and only 35% of claimed tokens hit exchanges in the first week.
- *Insight*: The initial distribution design appears to have created lasting selling pressure for 1inch, whereas CowSwap's fairer airdrop attracted longer-term holders.

3. Price & Valuation (CoinGecko)
- Over the past 12 months, **1INCH price fell 34%** while **COW token price rose 12%** (both indexed to 100 at start).
- Market cap of 1inch dropped from $680M to $450M; CowSwap's market cap grew from $210M to $340M.
- Despite still leading in volume, 1inch's valuation multiple (market cap / weekly volume = 0.21) is now lower than CowSwap's (0.24), suggesting the market is pricing in future growth for CowSwap.

4. Protocol Efficiency & User Retention (Dune custom query)
- Daily active traders on 1inch fell from 18k to 12k over the same period, while CowSwap's active traders increased from 4k to 11k.
- Average trade size on CowSwap ($2,300) is significantly larger than on 1inch ($520), indicating CowSwap is attracting higher-value "intent-based" trades, whereas 1inch remains dominant for retail-sized swaps.

```
## Conclusion

**1inch is still the volume king, but CowSwap is winning the narrative and structural gro
wth battle.**

The evidence from all five sources converges on a clear trend: 1inch's early-adopter adva
ntage is being gradually overtaken by CowSwap's fairer tokenomics and better retention of
high-value users. 1inch's market share erosion is not a random fluctuation—it is consiste
nt across two independent volume trackers (DeFiLlama, Dune), backed by on-chain transfer
data showing distribution-induced selling (Etherscan, The Graph), and reflected in relati
ve token underperformance (CoinGecko).

**Key takeaways for the broader DeFi aggregator space:**
- **Airdrop design has long-term consequences.** Uneven early distribution can become a p
ermanent headwind.
- **Volume alone is misleading.** A protocol can dominate in volume while losing mindshar
e and market cap.
- **Multi-source triangulation is essential.** Each data source answers a different piece
of the "why" behind the numbers.

**Next steps for deeper analysis** (optional):
- Build a unified dashboard tracking daily active addresses + volume + market cap per pro
tocol.
- Run a cohort analysis on Dune to see if 1inch's lost users migrated to CowSwap or left
aggregators entirely.

*All numbers in this notebook are placeholders. Replace with your actual query results be
fore publishing.*
```

You now have a template that shows **how** to weave evidence from different APIs into single, believable conclusions. Just swap out the placeholder numbers and adjust the narrative to match whatever your real data says. Good luck with the final write-up!

```
from dune_client.client import DuneClient
from dune_client.query import QueryBase

dune = DuneClient(DUNE_API_KEY)

DUNE_QUERY_ID = 7410340
```

```
DUNE_QUERY_ID = 4100 10

agg_df = None

try:
    result = dune.get_latest_result(DUNE_QUERY_ID)

    agg_df = pd.DataFrame(result.result.rows)
except Exception as e:
    print(f'Dune query unavailable ({type(e).__name__}).')

agg_df
```

AttributeError: 'numpy.float64' object has no attribute '4f'

Thought for 7 seconds

> We need to diagnose the error. The user tried to display `agg_df` (DataFrame) after fetching data from Dune. The error `AttributeError: 'numpy.float64' object has no attribute '4f'` suggests that some float formatting issue occurred when pandas tried to render the DataFrame. Possibly one of the columns contains numeric values that pandas' formatter misinterpreted due to a malformed format string (like a string `'4f'` being used as an attribute). This is unusual. Could be due to a corrupted environment or a specific data value that is not a number but a string like `'4f'`. Or perhaps the `result.rows` contains strange data.
>
> But the user's question is: they got an error. They need help fixing it. Also they might need a more robust way to fetch data from Dune. I should provide a solution: explain the error likely due to bad data types or a formatting directive being misinterpreted; show how to inspect the data safely; and suggest using `get_latest_result_dataframe` instead of manually constructing DataFrame from rows. Also use `try-except` and print the raw result to debug.
>
> Thus my answer will:
>
> 1. Explain the error: possibly a numeric column containing strings like `'4f'` that pandas tries to format with a float formatter but fails.
> 2. Provide a corrected code snippet using `get_latest_result_dataframe` which returns a proper DataFrame.
> 3. Add error handling and data inspection steps.
> 4. Show how to safely view the data.
>
> I'll also note that the import of `QueryBase` is unnecessary.

The error you're encountering (`'numpy.float64' object has no attribute '4f'`) is a strange formatting error that usually indicates **one of your numeric columns contains a string that looks like a format specifier** (e.g., `'4f'` instead of a number). This can happen if the Dune query returns malformed data—for example, a column that should have numbers actually returns strings like `"4f"` due to a SQL error or unexpected casting.

🐛 How to Fix It

The safest approach is to **inspect the raw data before converting to a DataFrame**, and

use `get_latest_result_dataframe()` which is the recommended method from the `dune-client` library (it handles type conversion better than manually building from `result.rows`).

Improved Code (with debugging)

```python
import pandas as pd
from dune_client.client import DuneClient

DUNE_API_KEY = "your_key_here"
dune = DuneClient(DUNE_API_KEY)

DUNE_QUERY_ID = 7410340

agg_df = None

try:
    # Use get_latest_result_dataframe() - returns a clean DataFrame
    agg_df = dune.get_latest_result_dataframe(DUNE_QUERY_ID)

    # Quick sanity check on data types
    print("DataFrame shape:", agg_df.shape)
    print("Column dtypes:\n", agg_df.dtypes)
    print("First 2 rows:\n", agg_df.head(2))

except Exception as e:
    print(f"Dune query failed ({type(e).__name__}): {e}")
    # Fallback: fetch raw rows and investigate
    try:
        result = dune.get_latest_result(DUNE_QUERY_ID)
        raw_rows = result.result.rows
        print(f"Raw row count: {len(raw_rows)}")
        if raw_rows:
            print("First raw row:", raw_rows[0])
        # Attempt to convert manually with explicit error handling
        agg_df = pd.DataFrame(raw_rows)
        # Try to force numeric columns if needed
        for col in agg_df.select_dtypes(include=['object']):
            agg_df[col] = pd.to_numeric(agg_df[col], errors='ignore')
    except Exception as e2:
```

```
        print(f"Fallback also failed: {e2}")

# Now safe to display
if agg_df is not None:
    # If the DataFrame is huge, use .head() or .info() instead of directly printing
    with pd.option_context('display.max_rows', 10, 'display.max_columns', None):
        print(agg_df.head(10))
else:
    print("No data loaded.")
```

🔍 Why the Error Happened

- `get_latest_result()` returns an object where `result.rows` is a list of dicts with raw values (often strings, integers, floats).
- When you call `pd.DataFrame(result.result.rows)`, pandas tries to infer dtypes. If a column contains a mixture of numbers and malformed strings (like `'4f'`), pandas might treat it as `object` dtype. Later, when rendering the DataFrame, a formatter (e.g., `'{:.4f}'.format`) is applied to a float element **but the element is actually a string** that looks like a number format – leading to the cryptic attribute error.

Common causes:

- A Dune query that accidentally returns a format string (e.g., `CAST(amount AS VARCHAR)` returns `'4f'` as literal text).
- An aggregator field that includes units or symbols (e.g., `'3.5M'` instead of `3500000`).

✅ Best Practices for Dune + Python

1. **Always use** `get_latest_result_dataframe()` – it handles type coercion and nulls more gracefully.
2. **Inspect the query on Dune's web UI** first. Run it and look at the output types.
3. **If you must use raw rows**, convert numeric columns explicitly with `pd.to_numeric(..., errors='coerce')`.
4. **Avoid printing the entire DataFrame** when it's large. Use `df.head()` or `df.info()`.

Once your DataFrame loads cleanly, you can proceed with the stacked bar / area charts

as discussed earlier. If the problem persists, share the first 2–3 rows of raw data (from `raw_rows[0]`) and the exact column names – I'll help you craft a custom parser.
